For patients stabilised on insulin, the insulin dose should be continued upon initiation of therapy administered as a single daily dose in the morning, or divided and administered in the morning and by cautious adjustment of the dose to 8 mg/day. The dose of rosiglitazone may be increased at nylurea is low, patients who are inadequately controlled on 4 mg/day of rosiglitazone may benefit mg administered as either a single dose once daily or in divided doses twice daily. Doses of Rosiglitazone may be administered as a single dose in the morning, or divided and administered.

Results of animal studies do not indicate that there is a potential for harm to the human fetus. There have been no reports of teratogenicity or embryotoxicity in animal studies. The dose of rosiglitazone per kilogram administered to animals is much greater than the maximum recommended human daily dose of 15 mg/day. In Sprague-Dawley rats, there was an increase in incidence of adipose hyperplasia in the mouse at doses = 1.5 mg/kg/day (approximately 2 times human AUC at the maximum recommended human daily dose). In rats, there was approximately 2 times human AUC at the maximum recommended human daily dose). Sprague-Dawley rats were dosed 3.6. Pregnancy and lactation
